ONE

PHILOSOPHY

Paris is built with the same *less is more* philosophy as Idiorm.

TWO

INSTALLATION

2.1 Packagist

This library is available through Packagist with the vendor and package identifier of j4mie/paris Please see the Packagist documentation for further information.

2.2 Download

You can clone the git repository, download idiorm.php or a release tag and then drop the idiorm.php file in the vendors/3rd party/libs directory of your project.

CONFIGURATION

3.1 Setup

Paris requires Idiorm. Install Idiorm and Paris somewhere in your project directory, and require both.

```
require_once 'your/path/to/idiorm.php';
require_once 'your/path/to/paris.php';
```

Then, you need to tell Idiorm how to connect to your database. For full details of how to do this, see 'Idiorm's documentation'_.

Briefly, you need to pass a Data Source Name connection string to the configure method of the ORM class.

```
ORM::configure('sqlite:./example.db');
```

You may also need to pass a username and password to your database driver, using the username and password configuration options. For example, if you are using MySQL:

```
ORM::configure('mysql:host=localhost;dbname=my_database');
ORM::configure('username', 'database_user');
ORM::configure('password', 'top_secret');
```

3.2 Model prefixing

Setting: Model::\$auto_prefix_models

To save having type out model class name prefixes whenever code utilises Model::for_table() it is possible to specify a prefix that will be prepended onto the class name.

The model prefix is treated the same way as any other class name when Paris attempts to convert it to a table name. This is documented in the Models section of the documentation.

Here is a namespaced example to make it clearer:

```
Model::$auto_prefix_models = '\\Tests\\';
Model::factory('Simple')->find_many(); // SQL executed: SELECT * FROM `tests_simple`
Model::factory('SimpleUser')->find_many(); // SQL executed: SELECT * FROM `tests_simple_user`
```

Note: It is possible to define the table name by setting \$_table in your individual model classes. As documented in the Models section of the documentation.

3.3 Further Configuration

The only other configuration options provided by Paris itself are the *\$_table* and *\$_id_column* static properties on model classes. To configure the database connection, you should use Idiorm's configuration system via the ORM::configure method.

If you are using multiple connections, the optional *\$_connection_key* static property may also be used to provide a default string key indicating which database connection in *ORM* should be used.

See 'Idiorm's documentation'_ for full details.

3.4 Query logging

Idiorm can log all queries it executes. To enable query logging, set the logging option to true (it is false by default).

ORM::configure('logging', true);

When query logging is enabled, you can use two static methods to access the log. ORM::get_last_query() returns the most recent query executed. ORM::get_query_log() returns an array of all queries executed.

MODELS

4.1 Model Classes

You should create a model class for each entity in your application. For example, if you are building an application that requires users, you should create a User class. Your model classes should extend the base Model class:

```
class User extends Model {
}
```

Paris takes care of creating instances of your model classes, and populating them with *data* from the database. You can then add *behaviour* to this class in the form of public methods which implement your application logic. This combination of data and behaviour is the essence of the Active Record pattern.

4.2 Database Tables

Your User class should have a corresponding user table in your database to store its data.

By default, Paris assumes your class names are in *CapWords* style, and your table names are in *lower-case_with_underscores* style. It will convert between the two automatically. For example, if your class is called CarTyre, Paris will look for a table named car_tyre.

If you are using namespaces then they will be converted to a table name in a similar way. For example \Models\CarTyre would be converted to models_car_tyre. Note here that backslashes are replaced with underscores in addition to the *CapWords* replacement discussed in the previous paragraph.

To override this default behaviour, add a **public static** property to your class called *\$_table*:

```
class User extends Model {
    public static $_table = 'my_user_table';
}
```

4.2.1 Auto Prefixing

To save having type out model class name prefixes whenever code utilises Model::for_table() it is possible to specify a prefix that will be prepended onto the class name.

See the Configuration documentation for more details.

4.3 ID Column

Paris requires that your database tables have a unique primary key column. By default, Paris will use a column called id. To override this default behaviour, add a **public static** property to your class called j_d_column :

```
class User extends Model {
    public static $_id_column = 'my_id_column';
}
```

Note - Paris has its *own* default ID column name mechanism, and does not respect column names specified in Idiorm's configuration.

ASSOCIATIONS

Paris provides a simple API for one-to-one, one-to-many and many-to-many relationships (associations) between models. It takes a different approach to many other ORMs, which use associative arrays to add configuration metadata about relationships to model classes. These arrays can often be deeply nested and complex, and are therefore quite error-prone.

Instead, Paris treats the act of querying across a relationship as a *behaviour*, and supplies a family of helper methods to help generate such queries. These helper methods should be called from within *methods* on your model classes which are named to describe the relationship. These methods return ORM instances (rather than actual Model instances) and so, if necessary, the relationship query can be modified and added to before it is run.

5.1 Summary

The following list summarises the associations provided by Paris, and explains which helper method supports each type of association:

5.1.1 One-to-one

Use has_one in the base, and belongs_to in the associated model.

5.1.2 One-to-many

Use has_many in the base, and belongs_to in the associated model.

5.1.3 Many-to-many

Use has_many_through in both the base and associated models.

Below, each association helper method is discussed in detail.

5.2 Has-one

One-to-one relationships are implemented using the has_one method. For example, say we have a User model. Each user has a single Profile, and so the user table should be associated with the profile table. To be able to find the profile for a particular user, we should add a method called profile to the User class (note that the method name here is arbitrary, but should describe the relationship). This method calls the protected has_one

method provided by Paris, passing in the class name of the related object. The profile method should return an ORM instance ready for (optional) further filtering.

```
class Profile extends Model {
}
class User extends Model {
    public function profile() {
        return $this->has_one('Profile');
    }
}
```

The API for this method works as follows:

```
// Select a particular user from the database
$user = Model::factory('User')->find_one($user_id);
// Find the profile associated with the user
$profile = $user->profile()->find_one();
```

By default, Paris assumes that the foreign key column on the related table has the same name as the current (base) table, with _id appended. In the example above, Paris will look for a foreign key column called user_id on the table used by the Profile class. To override this behaviour, add a second argument to your has_one call, passing the name of the column to use.

5.3 Has many

One-to-many relationships are implemented using the has_many method. For example, say we have a User model. Each user has several Post objects. The user table should be associated with the post table. To be able to find the posts for a particular user, we should add a method called posts to the User class (note that the method name here is arbitrary, but should describe the relationship). This method calls the protected has_many method provided by Paris, passing in the class name of the related objects. **Pass the model class name literally, not a pluralised version**. The posts method should return an ORM instance ready for (optional) further filtering.

```
class Post extends Model {
}
class User extends Model {
   public function posts() {
      return $this->has_many('Post'); // Note we use the model name literally - not a pluralised ve
   }
}
```

The API for this method works as follows:

```
// Select a particular user from the database
$user = Model::factory('User')->find_one($user_id);
```

```
// Find the posts associated with the user
$posts = $user->posts()->find_many();
```

By default, Paris assumes that the foreign key column on the related table has the same name as the current (base) table, with _id appended. In the example above, Paris will look for a foreign key column called user_id on the table used by the Post class. To override this behaviour, add a second argument to your has_many call, passing the name of the column to use.

5.4 Belongs to

}

The 'other side' of has_one and has_many is belongs_to. This method call takes identical parameters as these methods, but assumes the foreign key is on the *current* (base) table, not the related table.

```
class Profile extends Model {
   public function user() {
      return $this->belongs_to('User');
   }
}
class User extends Model {
```

The API for this method works as follows:

```
// Select a particular profile from the database
$profile = Model::factory('Profile')->find_one($profile_id);
// Find the user associated with the profile
```

\$user = \$profile->user()->find_one();

Again, Paris makes an assumption that the foreign key on the current (base) table has the same name as the related table with _id appended. In the example above, Paris will look for a column named user_id. To override this behaviour, pass a second argument to the belongs_to method, specifying the name of the column on the current (base) table to use.

5.5 Has many through

Many-to-many relationships are implemented using the has_many_through method. This method has only one required argument: the name of the related model. Supplying further arguments allows us to override default behaviour of the method.

For example, say we have a Book model. Each Book may have several Author objects, and each Author may have written several Books. To be able to find the authors for a particular book, we should first create an intermediary model. The name for this model should be constructed by concatenating the names of the two related classes, in alphabetical order. In this case, our classes are called Author and Book, so the intermediate model should be called AuthorBook.

We should then add a method called authors to the Book class (note that the method name here is arbitrary, but should describe the relationship). This method calls the protected has_many_through method provided by Paris, passing in the class name of the related objects. Pass the model class name literally, not a pluralised version. The authors method should return an ORM instance ready for (optional) further filtering.

```
class Author extends Model {
   public function books() {
      return $this->has_many_through('Book');
   }
}
class Book extends Model {
   public function authors() {
      return $this->has_many_through('Author');
   }
}
```

class AuthorBook extends Model {
}

The API for this method works as follows:

```
// Select a particular book from the database
$book = Model::factory('Book')->find_one($book_id);
// Find the authors associated with the book
$authors = $book->authors()->find_many();
// Get the first author
$first_author = $authors[0];
// Find all the books written by this author
$first_author books = $first_author->books()->find_many();
```

5.5.1 Overriding defaults

The has_many_through method takes up to four arguments, which allow us to progressively override default assumptions made by the method.

First argument: associated model name - this is mandatory and should be the name of the model we wish to select across the association.

Second argument: intermediate model name - this is optional and defaults to the names of the two associated models, sorted alphabetically and concatenated.

Third argument: custom key to base table on intermediate table - this is optional, and defaults to the name of the base table with _id appended.

Fourth argument: custom key to associated table on intermediate table - this is optional, and defaults to the name of the associated table with _id appended.

QUERYING

Querying allows you to select data from your database and populate instances of your model classes. Queries start with a call to a static *factory method* on the base Model class that takes a single argument: the name of the model class you wish to use for your query. This factory method is then used as the start of a *method chain* which gives you full access to Idiorm's fluent query API. See Idiorm's documentation for details of this API.

For example:

```
$users = Model::factory('User')
    ->where('name', 'Fred')
    ->where_gte('age', 20)
    ->find_many();
```

You can also use the same shortcut provided by Idiorm when looking up a record by its primary key ID:

\$user = Model::factory('User')->find_one(\$id);

The only differences between using Idiorm and using Paris for querying are as follows:

- 1. You do not need to call the for_table method to specify the database table to use. Paris will supply this automatically based on the class name (or the \$_table static property, if present).
- 2. The find_one and find_many methods will return instances of *your model subclass*, instead of the base ORM class. Like Idiorm, find_one will return a single instance or false if no rows matched your query, while find_many will return an array of instances, which may be empty if no rows matched.
- 3. Custom filtering, see next section.

You may also retrieve a count of the number of rows returned by your query. This method behaves exactly like Idiorm's count method:

\$count = Model::factory('User')->where_lt('age', 20)->count();

6.1 Getting data from objects, updating and inserting data

The model instances returned by your queries now behave exactly as if they were instances of Idiorm's raw ORM class.

You can access data:

```
$user = Model::factory('User')->find_one($id);
echo $user->name;
```

Update data and save the instance:

```
$user = Model::factory('User')->find_one($id);
$user->name = 'Paris';
$user->save();
```

To create a new (empty) instance, use the create method:

```
$user = Model::factory('User')->create();
$user->name = 'Paris';
$user->save();
```

To check whether a property has been changed since the object was created (or last saved), call the is_dirty method:

\$name_has_changed = \$person->is_dirty('name'); // Returns true or false

You can also use database expressions when setting values on your model:

```
$user = Model::factory('User')->find_one($id);
$user->name = 'Paris';
$user->set_expr('last_logged_in', 'NOW()');
$user->save();
```

Of course, because these objects are instances of your base model classes, you can also call methods that you have defined on them:

```
class User extends Model {
   public function full_name() {
      return $this->first_name . ' ' . $this->last_name;
   }
}
$user = Model::factory('User')->find_one($id);
echo $user->full_name();
```

To delete the database row associated with an instance of your model, call its delete method:

```
$user = Model::factory('User')->find_one($id);
$user->delete();
```

You can also get the all the data wrapped by a model subclass instance using the as_array method. This will return an associative array mapping column names (keys) to their values.

The as_array method takes column names as optional arguments. If one or more of these arguments is supplied, only matching column names will be returned.

```
class Person extends Model {
}
$person = Model::factory('Person')->create();
$person->first_name = 'Fred';
$person->surname = 'Bloggs';
$person->age = 50;
// Returns array('first_name' => 'Fred', 'surname' => 'Bloggs', 'age' => 50)
$data = $person->as_array();
// Returns array('first_name' => 'Fred', 'age' => 50)
$data = $person->as_array('first_name', 'age');
```

FILTERS

It is often desirable to create reusable queries that can be used to extract particular subsets of data without repeating large sections of code. Paris allows this by providing a method called filter which can be chained in queries alongside the existing Idiorm query API. The filter method takes the name of a **public static** method on the current Model subclass as an argument. The supplied method will be called at the point in the chain where filter is called, and will be passed the ORM object as the first parameter. It should return the ORM object after calling one or more query methods on it. The method chain can then be continued if necessary.

It is easiest to illustrate this with an example. Imagine an application in which users can be assigned a role, which controls their access to certain pieces of functionality. In this situation, you may often wish to retrieve a list of users with the role 'admin'. To do this, add a static method called (for example) admins to your Model class:

```
class User extends Model {
   public static function admins($orm) {
      return $orm->where('role', 'admin');
   }
}
```

You can then use this filter in your queries:

```
$admin_users = Model::factory('User')->filter('admins')->find_many();
```

You can also chain it with other methods as normal:

```
$young_admins = Model::factory('User')
         ->filter('admins')
         ->where_lt('age', 18)
         ->find_many();
```

7.1 Filters with arguments

You can also pass arguments to custom filters. Any additional arguments passed to the filter method (after the name of the filter to apply) will be passed through to your custom filter as additional arguments (after the ORM instance).

For example, let's say you wish to generalise your role filter (see above) to allow you to retrieve users with any role. You can pass the role name to the filter as an argument:

```
class User extends Model {
   public static function has_role($orm, $role) {
      return $orm->where('role', $role);
   }
}
```

```
$admin_users = Model::factory('User')->filter('has_role', 'admin')->find_many();
$guest_users = Model::factory('User')->filter('has_role', 'guest')->find_many();
```

These examples may seem simple (filter('has_role', 'admin') could just as easily be achieved using where('role', 'admin')), but remember that filters can contain arbitrarily complex code - adding raw_where clauses or even complete raw_query calls to perform joins, etc. Filters provide a powerful mechanism to hide complexity in your model's query API.

EIGHT

TRANSACTIONS

Paris (or Idiorm) doesn't supply any extra methods to deal with transactions, but it's very easy to use PDO's built-in methods:

```
// Start a transaction
ORM::get_db()->beginTransaction();
```

```
// Commit a transaction
ORM::get_db()->commit();
```

```
// Roll back a transaction
ORM::get_db()->rollBack();
```

For more details, see the PDO documentation on Transactions.

A WORD ON VALIDATION

It's generally considered a good idea to centralise your data validation in a single place, and a good place to do this is inside your model classes. This is preferable to handling validation alongside form handling code, for example. Placing validation code inside models means that if you extend your application in the future to update your model via an alternative route (say a REST API rather than a form) you can re-use the same validation code.

Despite this, Paris doesn't provide any built-in support for validation. This is because validation is potentially quite complex, and often very application-specific. Paris is deliberately quite ignorant about your actual data - it simply executes queries, and gives you the responsibility of making sure the data inside your models is valid and correct. Adding a full validation framework to Paris would probably require more code than Paris itself!

However, there are several simple ways that you could add validation to your models without any help from Paris. You could override the save() method, check the data is valid, and return false on failure, or call parent::save() on success. You could create your own subclass of the Model base class and add your own generic validation methods. Or you could write your own external validation framework which you pass model instances to for checking. Choose whichever approach is most suitable for your own requirements.

MIGRATIONS

Paris does not have native support for migrations, but some work has been done to integrate PHPMig. If you want to have migrations in your project then this is recommended route as Paris will never have migrations directly implemented in the core. Please refer to the Paris and Idiorm Philosophy for reasons why.

To integrate Paris with PHPMig you will need to follow their installation instructions and then configure it to use the Paris PDO instance:

```
$container['db'] = $container->share(function(){
    return ORM::get_db();
});
$container['phpmig.adapter'] = $container->share(function() use ($container) {
    return new Adapter\PDO\Sql($container['db'], 'migrations');
});
```

ELEVEN

MULITPLE CONNECTIONS

Paris now works with multiple database conections (and necessarily relies on an updated version of Idiorm that also supports multiple connections). Database connections are identified by a string name, and default to OrmWrapper::DEFAULT_CONNECTION (which is really ORM::DEFAULT_CONNECTION).

See Idiorm's documentation for information about configuring multiple connections.

The connection to use can be specified in two separate ways. To indicate a default connection key for a subclass of Model, create a public static property in your model class called *\$_connection_name*.

```
// A named connection, where 'alternate' is an arbitray key name
ORM::configure('sqlite:./example2.db', null, 'alternate');
class SomeClass extends Model
{
    public static $_connection_name = 'alternate';
}
```

The connection to use can also be specified as an optional additional parameter to OrmWrapper::for_table(), or to Model::factory(). This will override the default setting (if any) found in the \$_connection_name static property.

```
$person = Model::factory('Author', 'alternate')->find_one(1); // Uses connection named 'alternate'
```

The connection can be changed after a model is populated, should that be necessary:

```
$person = Model::factory('Author')->find_one(1); // Uses default connection
$person->orm = Model::factory('Author', 'alternate'); // Switches to connection named 'alternate'
$person->name = 'Foo';
$person->save(); // *Should* now save through the updated connection
```

Queries across multiple connections are not supported. However, as the Paris methods has_one, has_many and belongs_to don't require joins, these *should* work as expected, even when the objects on opposite sides of the relation belong to diffrent connections. The has_many_through relationship requires joins, and so will not reliably work across different connections.

TWELVE

INDICES AND TABLES

- genindex
- modindex
- search
